

The maximum length of a segment satisfying a monotonic predicate

For a given sequence  $f(i: 0 \leq i < N)$ ,  $f(i: x \leq i < y)$  with  $0 \leq x \leq y \leq N$  is called "a segment of length  $y-x$ ".

Let, with  $0 \leq x \leq y \leq N$ ,  $Bx y$  be some predicate on segment  $f(i: x \leq i < y)$  such that

$$\underline{A}(x, h, k, y: 0 \leq x \leq h \leq k \leq y \leq N: B h k \vee \neg B x y) ;$$

such a predicate is called "monotonic". We know many examples of monotonic predicates, such as:

- all elements positive
- all elements equal
- ascending
- not containing adjacent, non-empty, equal sub-segments
- having its first differences of alternating signs.

For a  $B$  that holds for any empty segment we shall derive a program establishing  $R$  given by

$$R: \quad c = \underline{MAX}(x, y: 0 \leq x \leq y \leq N \wedge B x y: y-x) .$$

To begin with we approach the problem in the standard way by introducing a variable  $n$  satisfying  $P_0$  given by

$$P_0: \quad c = \underline{MAX}(x, y: 0 \leq x \leq y \leq n \wedge B x y: y-x) \wedge 0 \leq n \leq N ,$$

which yields a program of the structure

$\llbracket n: \text{int}; c, n := 0, 0 \{ \text{invariant } P_0 \}$   
 $; \underline{\text{do}} \ n \neq N \rightarrow$   
     "increase  $n$  by 1 under invariance of  $P_0$ "  
    $\underline{\text{od}}$   
 $\rrbracket$  .

From  $P_0 \wedge n \neq N$  we conclude

$$\underline{\text{MAX}}(x, y: 0 \leq x \leq y \leq n+1 \wedge B \ x \ y: y-x) = \underline{\text{MAX}}(x: 0 \leq x \leq n+1 \wedge B \ x \ (n+1): n+1-x) \underline{\text{max}} \ c ;$$

for the sake of convenience we rewrite the last line as

$$(n+1 - \underline{\text{MIN}}(x: 0 \leq x \leq n+1 \wedge B \ x \ (n+1): x)) \underline{\text{max}} \ c ,$$

which suggests the introduction of a variable  $h$  satisfying  $P_1$ , given by

$$P_1: \ h = \underline{\text{MIN}}(x: 0 \leq x \leq n \wedge B \ x \ n: x) .$$

This yields a program of the structure

$\llbracket n, h: \text{int}; c, n, h := 0, 0, 0 \{ \text{invariant } P_0 \wedge P_1 \}$   
 $; \underline{\text{do}} \ n \neq N \rightarrow$   
     "establish  $P_1(n+1/n)$ "  
      $; c := (n+1-h) \underline{\text{max}} \ c \{ P_0(n+1/n) \}$   
      $; n := n+1 \{ P_0 \wedge P_1 \}$   
    $\underline{\text{od}}$   
 $\rrbracket$  .

Without exploiting any property of  $B$  (beyond the fact that it holds for the empty segment), the Linear Search Theorem tells us that there is only one way of establishing  $P_1(n+1/n)$ , viz.

$h:=0$ ; do  $\neg B \ h \ (n+1) \rightarrow h:=h+1$  od ,

which —disregarding the evaluations of  $B$ — gives in general rise to a quadratic algorithm.

From the monotonicity of  $B$ , however, we can conclude that the solution of the equation  $h:P_1$  is at most the solution of  $h:P_1(n+1/n)$ ; hence, establishing  $P_1(n+1/n)$  can be implemented by

do  $\neg B \ h \ (n+1) \rightarrow h:=h+1$  od ,

which —again disregarding the evaluations of  $B$ — gives rise to a linear algorithm.

Note. From the above analysis follows that the monotonicity requirement on  $B$  is stronger than necessary: a "one-sided" monotonicity

$\underline{A}(x, k, y: 0 \leq x \leq k \leq y \leq N: B \ x \ k \vee \neg B \ x \ y)$

would have sufficed. An example of such a  $B$  is

$B \ x \ y \equiv \underline{A}(j: x \leq j < y: f \ x \leq f \ j)$  .

(End of Note.)

\* \* \*

Three remarks are in order. We have postulated that  $B$  holds for the empty segment because —see  $R$ — we did not care to define MAX over an empty bag. If  $B$  holds for any one-element segment, it is often convenient to deal with  $N=0$  separately; for  $N>0$ , the repetition can then be initialized with  $n=1$  and has  $h < n$  as a further invariant.

Secondly, the analytical structure of  $B$  is, thanks to some transitivity, often such that the net effect of

$$\underline{\text{do}} \ \neg B \ h \ (n+1) \rightarrow h := h+1 \ \underline{\text{od}}$$

can be captured by a modest alternative statement, say of the form

$$\text{if } \dots \rightarrow \text{skip} \ \square \ \dots \rightarrow h := n \ \text{fi} \ .$$

Thirdly, the assignment statement

$$c := (n+1-h) \ \underline{\text{max}} \ c$$

is equivalent to a skip in the case  $n+1-h \leq c$ , a situation implied by  $N-h \leq c$ . Once established, however,  $N-h \leq c$  is an invariant of the repetition; hence we can strengthen the guard by its negation  $h+c < N$ . But since  $n \leq h+c$  is a further invariant of the repetition  $n \neq N \wedge h+c < N$  can be simplified to just  $h+c < N$ .

\* \* \*

By way of illustration we give the solution for

$$B \ x \ y \equiv \underline{A}(j: x \leq j < y: f^x \leq f^j) \ .$$

$$\text{if } N=0 \rightarrow c := 0$$

$$\square \ N > 0 \rightarrow [n, h: \text{int}; c, n, h := 1, 1, 0$$

$$\ ; \ \underline{\text{do}} \ h+c < N \rightarrow$$

$$\quad \text{if } f(n) \geq f(h) \rightarrow \text{skip} \ \square \ f(n) < f(h) \rightarrow h := n \ \text{fi}$$

$$\ ; \ n := n+1; c := (n-h) \ \underline{\text{max}} \ c$$

$\underline{\text{od}}$

]

fi .

The above  $\mathcal{B}$  is one of one-sided monotonicity.  
Had we chosen

$$\mathcal{B} \times y \equiv \underline{A}(j: x \leq j < y: f_x = f_j)$$

we would have posed The Plateau Problem (see [0], p. 203, which deals with the special case that the given sequence is ordered). Its solution is obtained by replacing the inner alternative statement in the above by

$$\text{if } f(n) = f(h) \rightarrow \text{skip} \quad \parallel \quad f(n) \neq f(h) \rightarrow h := n \quad \text{fi} \quad .$$
